Context-sensitive interprocedural data-flow analysis -Classical methods

Call-string

- Sharir and Pnueli's k-call string method that maps a call string to its *k*-length suffix.
- Emami *et al.*'s method of reducing recursive paths in a call string by a single node.
- Procedure summary
- Inlining

イロト 不得 とくほ とくほ とうほ

Assumptions of call string based approaches

- The program uses special instructions like call and ret that can be identified and paired statically.
- Valid/invalid paths in ICFG can be described in terms of appropriate pairing of call-ret edges.

・ロト ・ 同ト ・ ヨト ・ ヨト … ヨ

Call and Ret are atomic in the sense that they:

- Transfer control; and
- Change context

(日) (圖) (E) (E) (E)

Call and Ret can be obfuscated using instructions that transfer control and change context separately. Call obfuscation can be employed by:

- Malware writers ⇒ to hide malicious behavior and to evade detection.
- Software developers ⇒ to protect intellectual property and to increase security.

イロン 不得 とくほ とくほ とうほ

Call obfuscation using *push/ret* instructions

Main:

| L1: | PUSH | 4 | |
|------|------|---------|-------|
| L2: | PUSH | 2 | |
| L3: | PUSH | offset | [L6] |
| L4: | PUSH | offset | [L13] |
| L5: | RET | | |
| L6: | PUSH | 6 | |
| L7: | PUSH | 4 | |
| L8: | PUSH | offset | [L11] |
| L9: | PUSH | offset | [L13] |
| L10: | RET | | |
| L11: | PUSH | 0 | |
| L12: | CALL | ExitPro | ocess |

Max:

| L13: | MOV | eax, | [esp+4] |
|------|-----|------|---------|
| L14: | MOV | ebx, | [esp+8] |
| L15: | CMP | eax, | ebx |
| L16: | JG | L18 | |
| L17: | MOV | eax, | ebx |
| L18: | RET | 8 | |

Call obfuscation using push/jmp instructions

Main:

| L1: | PUSH | 4 |
|------|------|-------------|
| L2: | PUSH | 2 |
| L3: | PUSH | offset [L5] |
| L4: | JMP | Max |
| L5: | PUSH | 6 |

Max:

| L11: | MOV | eax, | [esp+4] |
|------|-----|------|---------|
| L12: | MOV | ebx, | [esp+8] |
| L13: | CMP | eax, | ebx |
| L14: | JG | L16 | |
| L15: | MOV | eax, | ebx |
| L16: | RET | 8 | |

Classical call string based analyses are not directly applicable for context-sensitive analysis of binaries that have obfuscated calls. This is because:

 They are tied to semantics of procedure call and return statements of high-level languages, and therefore, call and ret instructions of assembly language.

・ロト ・ 同ト ・ ヨト ・ ヨト … ヨ

Objective: Design of a context-sensitive analysis based on program semantics and abstract interpretation resilient from call and ret obfuscation attacks.

イロト 不得 とくほ とくほ とうほ

- Context abstractions (generic versions independent of ICFG based definitions)
- Context-trace semantics (can not rely on ICFG based soundness results)
- Language (a simple assembly language without call and ret)
- Stack context (to model change of context)
- Transfer of control (is modeled using value-set analysis)
- Derive the context sensitive analyzer from context-insensitive one
- Prove soundness of our analysis

◆□▶ ◆□▶ ◆三▶ ◆三▶ ● ○ ○ ○

Generalized notion of contexts

• Opening and closing instructions are defined by:

- $(\subseteq I the set of instructions that open contexts.$
-) \subseteq *I* the set of instructions that close contexts.
- For example, in the conventional interprocedural analysis, the set (contains the call instructions and) contains the ret instructions.
- A context-string is a sequence of instructions that open contexts, represented by (|* ⊆ *I**.

k-context

- Let (^k represent the set of sequences of opening contexts of length ≤ k and k + 1 length sequences created by appending ⊤ = ∐(to k-length sequences of opening contexts.
- An element of (^k is called a *k*-context. We can establish a map α_k : (^{*}→ (^k as:

$$\alpha_k \ \nu \triangleq \begin{cases} \nu & \text{if } |\nu| \le k \\ \nu_k . \top & \text{otherwise, where } \exists \nu' : \nu = \nu_k \land |\nu_k| = k. \end{cases}$$

• (* and (k form a Galois insertion with the abstraction map α_k

(日)

- For example, the term *c*⁺ represents all cyclic context strings from *c* to *c*.
- A map α_ℓ : (*→ (ℓ can be defined such that (* and (ℓ form a Galois insertion with the abstraction map α_ℓ.

・ロ・・聞・・ヨ・・ヨ・ シック・

- A context-trace is a pair of a context string and a trace (ν, σ) ∈ ((*×Σ*).
- The set of all context-traces of a program, denoted by
 ρ(((*×Σ*)) ≡ ((*→ φ(Σ*)), gives its context-trace semantics.

Mapping Call and Ret in our language

• An instruction "*Call I*" may be mapped to the following sequence of instructions in our language:

$$l_0: esp = esp - 1 \cdot eip = l_1$$

 $l_1: *esp = l_2 \cdot eip = l$

where l_2 is the address of the instruction after the call instruction. It is not necessary that these two instructions appear contiguously in code.

• A *Ret* instruction may be mapped to the following instruction in our language:

$$l_0: esp = esp + 1$$
. $eip = *esp$

・ロト ・ 同ト ・ ヨト ・ ヨト … ヨ

- Idea: To have the information about instructions that manipulate the stack pointer as a part of the context.
- The stack context can be described as the set of opening contexts and closing contexts represented by domains (*asm* ⊆ *I* × N and *)asm* ⊆ *I* × N resp. that are defined as:

 $(|_{asm} \triangleq \{(i, n) \mid \exists \delta, \delta' : \delta' \in (\mathcal{I} \ i \ \delta) \land (\delta' \ esp) = (\delta \ esp) - n \}$ $)_{asm} \triangleq \{(i, n) \mid \exists \delta, \delta' : \delta' \in (\mathcal{I} \ i \ \delta) \land (\delta' \ esp) = (\delta \ esp) + n \}$

A context string is a sequence belonging to (*asm.
 Abstractions k-context and I-context can be applied to (*asm to reduce the complexity of the analysis.

・ロン・日本・ビン・ビン・ ビー うぐつ

- Upon execution of each instruction the instruction pointer register, *eip*, is updated with the label (a numerical value) of the next instruction to be executed.
- The value of the label may be computed from an expression involving values of registers and memory locations.
- We use Balakrishnan and Reps' Value-Set Analysis (VSA) to recover information about the contents of memory locations and registers. VSA uses the domain *RIC* = N × Z × Z to abstract ℘(Z).

イロン 不良 とくほう 不良 とうほう

The analysis is derived from a chain of Galois connections linking the concrete domain $\wp((I \times Store)^*)$ to the analysis domain $I \rightarrow AbStore$. The steps of the derivation are:

- The set ℘((*I* × Store)*), called set of traces, is approximated to trace of sets, represented by (℘(*I* × Store))*.
- The trace of sets is equivalent to (*I* → ℘(*Store*))*. This sequence of mapping of instructions to set of stores can be approximated to *I* → ℘(*Store*).
- Finally, a Galois connection between ℘(*Store*) and *AbStore* completes the analysis.

・ロト ・ 同 ト ・ 三 ト ・ 三 ・ つへの

Starting from concrete domain $(\stackrel{*}{asm} \xrightarrow{\Pi_{asm}} \wp(\Sigma^*)$ and the domain for Venable *et al.*'s context insensitive analyzer $I \rightarrow R + L \rightarrow ASG \times RIC$, we obtain our context sensitive analyzer analyzer $\hat{(}_{asm}^{\ell} \rightarrow I \rightarrow R + L \rightarrow RIC$ using the following results:

$$\bigcirc \ (^*_{asm} \sqsubseteq \hat{(}^\ell_{asm}$$

$$\bigcirc \wp(\mathbb{Z}) \sqsubseteq \mathsf{RIC}$$

イロン 不良 とくほう 不良 とうほう

- The concrete context-trace semantics is given by the least fixpoint of the function $\mathcal{F}_{c}: (\underset{asm}{*} \xrightarrow{\Pi_{asm}} \wp(\Sigma^{*}) \longrightarrow (\underset{asm}{*} \xrightarrow{\Pi_{asm}} \wp(\Sigma^{*}), \text{where}$ $\Sigma = I \times R + L \rightarrow \mathbb{Z}.$
- The context-trace semantics of the context-sensitive analyzer is given by the least fixpoint of the function $\mathcal{F}^{\#}$: $(\hat{l}_{asm}^{\ell} \rightarrow I \rightarrow R + L \rightarrow RIC) \longrightarrow (\hat{l}_{asm}^{\ell} \rightarrow I \rightarrow R + L \rightarrow RIC).$

(日)

Lemma

$$(\!\!|_{asm}^* \xrightarrow{\Pi_{asm}} \wp(\Sigma^*) \sqsubseteq \widehat{(\!\!|_{asm}^\ell \to I \to R + L \to RIC}.$$

It follows from the lemma and the fixpoint transfer theorem that $\mathcal{F}^{\#}$ is a sound approximation of \mathcal{F}_{c} .

(日)

DOC (Detector of Obfuscated Calls)

- We implemented our derived analysis in a tool called DOC.
- We studied the improvements in analysis of obfuscated code resulting from the use of our ℓ-context-sensitive version of Venable *et al.*'s analysis against its context-insensitive version.
- We performed the analysis using two sets of programs:
 - Programs in the first set were hand-crafted with a certain known obfuscated calling structure.
 - The second set contains W32.Evol.a, a metamorphic virus that employs call obfuscation.

- Developed a method for performing context sensitive analysis of binaries in which calling contexts cannot be discerned.
- Systematically derived generic versions of Sharir and Pnueli's k-suffix call-strings abstractions and Emami *et al.*'s strategy of abstracting calling-contexts (referred to as *l*-context in our work).
- Introduced the concept of stack-context, used in *lieu* of calling context, to perform context sensitive analysis of binaries that use call obfuscation.
- Proposed a general method for deriving sound context-sensitive analysis from context-insensitive one.
