

Abstract interpretation, re-reloaded

Jan Midtgaard

Week 4, Abstract Interpretation

Aarhus University, Q4 - 2012

With figures courtesy of David A. Schmidt, Patrick and Radhia Cousot.

Last time

A first in-depth look at abstract interpretation based on Cousot-Cousot:JLP92.

- Foundations: Fixed points, Galois connections, . . .
- The Galois approach and friends: closure operators, Moore families, . . .
- From collecting semantics to analysis (soundness, optimality, completeness)
- The first step towards analysing Plotkin's three counter machine

Today

More approximation methods for abstract interpretation (Cousot-Cousot:JLP92):

- Partitioning
- Relational and attribute independent analysis
- Inducing, abstracting, approximating fixed points
- Widening, narrowing
- Forwards/backwards analysis

More fun with Plotkin's three counter machine

Partitioning

Partitioning

Definition. Let L be a set of labels. A *partition* of a complete lattice $\langle C; \sqsubseteq, \perp, \top, \sqcup, \sqcap \rangle$ is a function $\delta : L \rightarrow C$ that (a) covers \mathbf{C} : $\top = \sqcup_{l \in L} \delta(l)$, and (b) is disjoint: $\forall l, l' \in L : l \neq l' \implies \delta(l) \sqcap \delta(l') = \perp$

Proposition. Let $\delta : L \rightarrow C$ be a partition of a complete lattice $\langle C; \sqsubseteq, \perp, \top, \sqcup, \sqcap \rangle$. Then the abstract domain $A = \prod_{l \in L} \{c \sqcap \delta(l) \mid c \in C\}$ ordered componentwise $a \leq a' \iff \forall l \in L : a(l) \sqsubseteq a'(l)$ forms a Galois connection:

$$\langle C; \sqsubseteq \rangle \begin{array}{c} \xleftarrow{\gamma} \\ \xrightarrow{\alpha} \end{array} \langle A; \leq \rangle$$

where $\alpha(c) = \lambda l. c \sqcap \delta(l)$ $\gamma(a) = \sqcup_{l \in L} a(l)$

By reducing the domain we can obtain a Galois surj.

Example: partitioning

Intuitively, we divide a set into a number of regions:

For example, the first abstraction of the 3 counter machine collecting semantics, groups quadruples with same pc : $L = PC$

$$\delta(pc) = \{ \langle pc, xv, yv, zv \rangle \mid xv \in \mathbb{N}_0, yv \in \mathbb{N}_0, zv \in \mathbb{N}_0 \}$$

$$\wp(PC \times \mathbb{N}_0 \times \mathbb{N}_0 \times \mathbb{N}_0) \xleftrightarrow[\alpha]{\gamma} PC \rightarrow \wp(PC \times \mathbb{N}_0 \times \mathbb{N}_0 \times \mathbb{N}_0)$$

Relational vs. independent attribute analysis

Relational vs. independent attribute analysis

Definition. We say an analysis is *attribute independent*, if attributes are analysed independently of each other.

For example, the Parity analysis of x , y , and z we will develop, analyses the possible values of each variable in isolation.

Definition. We say an analysis is *relational*, if it can determine relations between attributes.

For example, imagine an analysis that can determine x is odd if and only if y is even.

The loss of information in joins

Consider the following Sign domain (a variant of the two Sign domains we studied last week):

Observe how γ doesn't preserve \sqcup .

Disjunctive/down-set completion

Given a Galois connection we can improve it, by considering sets of elements:

Proposition. Given a Galois connection

$\langle \wp(C); \sqsubseteq \rangle \xrightleftharpoons[\alpha]{\gamma} \langle A; \leq \rangle$ between complete lattices:

$\langle \wp(C); \sqsubseteq, \emptyset, \overset{\alpha}{C}, \cup, \cap \rangle$ and $\langle A; \leq, \perp, \top, \vee, \wedge \rangle$ we can

replace A by $\wp_{\downarrow}(A) = \{\downarrow S \mid S \subseteq A\}$ to form another Galois connection:

$$\langle \wp(C); \sqsubseteq \rangle \xrightleftharpoons[\alpha^{\wp}]{\gamma^{\wp}} \langle \wp_{\downarrow}(A); \sqsubseteq \rangle$$

where $\downarrow S = \{a \in A \mid \exists a' \in S : a \leq a'\}$

$$\alpha^{\wp}(cs) = \cap \{as \mid cs \subseteq \gamma^{\wp}(as)\} = \downarrow \{\alpha(\{c\}) \mid c \in cs\}$$

$$\gamma^{\wp}(as) = \gamma(as) = \sqcup_{a \in as} \gamma(a)$$

Disjunctive completion to the rescue

The completion of the earlier Sign domain:

This domain is more expressive, however exponentially larger than the starting point.

In particular, it now preserves \sqcup (from Sign)

Q: What do we obtain by domain reduction?

Not always a free lunch...

Disjunctive completion may not provide an improvement:

Q: What do we obtain by domain reduction?

From attribute independent to relational analysis

Observation: Given n independent analyses, the disjunctive completion of their reduced product provides a *relational analysis*.

Example: Consider the disjunctive completion of the reduced product for Parity, for two variables x and y .

The resulting domain can express “ x is odd if and only if y is even”:

$$\begin{aligned} &\downarrow \{ \langle odd, even \rangle, \langle even, odd \rangle \} \\ &= \{ \langle odd, even \rangle, \langle even, odd \rangle, \dots \} \end{aligned}$$

Inducing, abstracting, and approximating fixed points

Fixed point inducing using Galois connections

Proposition. If $\langle C; \sqsubseteq \rangle \xleftrightarrow[\alpha]{\gamma} \langle A; \leq \rangle$ is a Galois connection between posets $\langle C; \sqsubseteq, \sqcup \rangle$ and $\langle A; \leq, \vee \rangle$, $T : C \rightarrow C$ is such that $\text{lfp } T = \bigsqcup_{n \geq 0} T^n(\perp)$, $\alpha(\perp_c) = \perp_a$, $T^\# : A \rightarrow A$ is such that $\alpha \circ T = T^\# \circ \alpha$ then $\alpha(\text{lfp } T) = \bigvee_{n \geq 0} T^{\#n}(\perp_a)$ and $\bigvee_{n \geq 0} T^{\#n}(\perp_a)$ is a fixed point of $T^\#$. If $T^\# : A \rightarrow A$ is monotone, it is furthermore the *least* fixed point ($\geq \perp_a$).

Note: this proposition concerns a *complete approximation*.

Illustration of induced fixed point

Proposition. If $\langle C; \sqsubseteq, \perp_c, \top_c, \sqcup, \sqcap \rangle$ and $\langle A; \leq, \perp_a, \top_a, \vee, \wedge \rangle$, are complete lattices, $\langle C; \sqsubseteq \rangle \xrightleftharpoons[\alpha]{\gamma} \langle A; \leq \rangle$ and $F : C \rightarrow C$ is monotone, then $\alpha(\text{lfp } F) \leq \text{lfp}(\alpha \circ F \circ \gamma)$

Note: this proposition concerns an *optimal approximation* (akin to what you did for today).

Proposition. If $\langle A; \leq, \perp_a, \top_a, \vee, \wedge \rangle$ is a complete lattice, $T^\#, T^{\#'} : A \rightarrow A$ are monotone functions and $T^\# \leq T^{\#'}$, then $\text{lfp } T^\# \leq \text{lfp } T^{\#'}$.

Read: any monotone, upward judgement of the above composition will be fine.

Illustration of approximated fixed point

Widening/narrowing reloaded

Narrowing motivation

We are after a (finite) approximation sequence $\check{X}^0 \geq \check{X}^1 \geq \check{X}^2 \geq \dots \geq \check{X}^n \geq \text{lfp } T^\#$ of the least fixed point (from above).

We could start from, e.g., $\check{X}^0 = \top$.

For the inductive step, not much is available: the previous iterate \check{X}^k and the function $T^\#$. Assuming $\text{lfp } T^\# \leq \check{X}^k$ and $T^\#$ is monotone, we want to ensure $\text{lfp } T^\# \leq \check{X}^{k+1}$.

The narrowing operator Δ simply combines the available information:

$$\check{X}^{k+1} = \check{X}^k \Delta T^\#(\check{X}^k)$$

Narrowing definition

Definition. A narrowing operator Δ satisfies the following:

- For all $x, y : (x \Delta y) \leq x$ (ensure decr. seq.)
- For all $x, y, z : x \leq y \wedge x \leq z \implies x \leq (y \Delta z)$
(keep above)
- For any decreasing chain X_i the alternative chain defined as $\check{X}^0 = X_0$ and $\check{X}^{k+1} = \check{X}^k \Delta X_{k+1}$ stabilizes after a finite number of steps.
(terminate)

Example: interval narrowing

Consider the domain of intervals: $\langle \wp(\mathbb{Z}); \subseteq \rangle \xrightleftharpoons[\alpha]{\gamma} \langle Interval; \sqsubseteq \rangle$
defined as follows:

$$Interval = \{[l, u] \mid l \in \mathbb{Z} \cup \{-\infty\} \wedge u \in \mathbb{Z} \cup \{+\infty\} \wedge l \leq u\} \cup \emptyset$$
$$[a, b] \sqsubseteq [c, d] \iff c \leq a \wedge b \leq d$$
$$\alpha(\emptyset) = \emptyset$$
$$\alpha(X) = [\min X, \max X] \quad \min \mathbb{Z} = -\infty \quad \max \mathbb{Z} = +\infty$$

Strictly decreasing interval chains can be infinite:

$$[0, +\infty] \supset [1, +\infty] \supset [2, +\infty] \supset \dots$$

Hence we need a narrowing operator:

$$\emptyset \Delta I = \emptyset \quad I \Delta \emptyset = \emptyset$$
$$[a, b] \Delta [c, d] = [\text{if } a = -\infty \text{ then } c \text{ else } a, \text{ if } b = +\infty \text{ then } d \text{ else } b]$$

Downward iteration with narrowing

Proposition. If $T^\# : A \rightarrow A$ is a monotone function, and $\Delta : A \times A \rightarrow A$ is a narrowing operator and $T^\#(a) = a \leq a'$ then $\check{X}^0 = a', \dots, \check{X}^{k+1} = \check{X}^k \Delta T^\#(\check{X}^k)$ converges with limit $\check{X}^n, n \in \mathbb{N}$ such that $a \leq \check{X}^n \leq a'$.

Intuition: this decreasing chain is finite and may take us closer to $T^\#$'s fixed point from above.

Note: In a complete lattice, if all strictly decreasing chains are finite, we can use $\Delta = \sqcap$.

Widening motivation

We aim for a better initial approximation than \top .

We are after a (finite) approximation sequence $\hat{X}^0 \leq \hat{X}^1 \leq \hat{X}^2 \leq \dots \leq \hat{X}^n \geq \text{lfp } T^\#$ of the least fixed point (starting below, ending above).

We could, e.g., try to iterate *above* a standard fixed point iteration: $X^0 = \perp, X^{k+1} = T^\#(X^k)$ towards $\text{lfp } T^\#$.

Hence start from $\hat{X}^0 = \perp$

and use the widening operator ∇ to combine the available information:

$$\hat{X}^{k+1} = \hat{X}^k \nabla T^\#(\hat{X}^k)$$

Widening definition

Definition. A widening operator satisfies the following:

- For all $x, y : x \leq (x \nabla y) \wedge y \leq (x \nabla y)$
(keep above)
- For any increasing chain $X_0 \sqsubseteq X_1 \sqsubseteq X_2 \sqsubseteq \dots$ the alternative chain defined as $\hat{X}^0 = X_0$ and $\hat{X}^{k+1} = \hat{X}^k \nabla X_{k+1}$ stabilizes after a finite number of steps.

Example: interval widening

Consider again the domain of intervals:

$$\langle \wp(\mathbb{Z}); \sqsubseteq \rangle \begin{array}{c} \xleftarrow{\gamma} \\ \xrightarrow{\alpha} \end{array} \langle \textit{Interval}; \sqsubseteq \rangle$$

For intervals strictly increasing chains can be infinite:

$$[0, 0] \sqsubset [0, 1] \sqsubset [0, 2] \sqsubset \dots$$

Hence we need a widening operator:

$$\emptyset \nabla I = I \qquad I \nabla \emptyset = I$$

$$[a, b] \nabla [c, d] = [\text{if } c < a \text{ then } -\infty \text{ else } a, \text{ if } d > b \text{ then } +\infty \text{ else } b]$$

Upward iteration with widening

Proposition. If $T^\# : A \rightarrow A$ is a monotone function, and $\nabla : A \times A \rightarrow A$ is a widening operator then $\hat{X}^0 = \perp, \dots, \hat{X}^{k+1} = \hat{X}^k \nabla T^\#(\hat{X}^k)$ converges with limit $\hat{X}^n, n \in \mathbb{N}$ such that $\text{lfp } T^\# \leq \hat{X}^n$.

Note: In a complete lattice, if all strictly increasing chains are finite, we can use $\nabla = \sqcup$.

We don't actually need to widen in such a situation.

Combining widening/narrowing iteration

Forwards/backwards analysis

Transition systems with final states

All though the transition system definition from week 1 included final states we haven't used them much:

Definition. A transition system is a quadruple $\langle S, I, F, \rightarrow \rangle$, where

- S is a set of states
- $I \subseteq S$ is a set of initial states
- $F \subseteq S$ is a set of final states ($\forall s \in F, s' \in S : s \not\rightarrow s'$)
- $\rightarrow \subseteq S \times S$ is a transition relation relating a state to its (possible) successors

Forwards collecting semantics (1/2)

Descendants of initial states (aka reachable states):

Forwards collecting semantics (2/2)

The forwards (top-down) collecting semantics can be expressed as a fixed point:

$$\begin{aligned} \text{lfp } T \text{ where } T(X) &= I \cup \{s \mid \exists s' \in X : s' \rightarrow s\} \\ &= I \cup \text{post}[\rightarrow](X) \end{aligned}$$

with

$$\text{post}[r](X) = \{s \mid \exists s' \in X : \langle s', s \rangle \in r\}$$

Note: here we are using the letter T for the transition function, as F is reserved for final states...

Backwards collecting semantics (1/2)

Ascendants of final states:

Backwards collecting semantics (2/2)

The backwards (bottom-up) collecting semantics can also be expressed as a fixed point:

$$\begin{aligned} \text{lfp } B \text{ where } B(X) &= F \cup \{s \mid \exists s' \in X : s \rightarrow s'\} \\ &= F \cup \text{pre}[\rightarrow](X) \end{aligned}$$

with

$$\text{pre}[r](X) = \{s \mid \exists s' \in X : \langle s, s' \rangle \in r\}$$

Forwards/backwards collecting semantics (1/2)

Descendants of initial states which are also ascendants of final states:

Forwards/backwards collecting semantics (2/2)

This set of states can be expressed as the intersection of the two fixed points just defined:

$$\text{lfp } T \cap \text{lfp } B$$

The above is not computable in general, but the intuition is:

1. “run program forwards”,
2. “run program backwards”,
3. intersect.

We can express forwards/backward collecting semantics in several ways:

Proposition. Given a transition system $\langle S, I, F, \rightarrow \rangle$ with $X \subseteq S$, we have

1. $pre[\rightarrow](X) \cap lfp T \subseteq pre[\rightarrow](X \cap lfp T)$
 2. $post[\rightarrow](X) \cap lfp B \subseteq post[\rightarrow](X \cap lfp B)$
- $$lfp T \cap lfp B$$
3. $= lfp(\lambda X. lfp T \cap B(X))$
 4. $= lfp(\lambda X. lfp B \cap T(X))$
 5. $= lfp(\lambda X. lfp T \cap lfp B \cap B(X))$
 6. $= lfp(\lambda X. lfp T \cap lfp B \cap T(X))$

Forwards/backwards analysis

Once we move to an abstract domain, a sequence akin to the alternative characterizations is more precise:

Proposition. If $\langle C; \sqsubseteq, \perp_c, \top_c, \sqcup, \sqcap \rangle$ and $\langle A; \leq, \perp_a, \top_a, \vee, \wedge \rangle$, are complete lattices, $\langle C; \sqsubseteq \rangle \xrightleftharpoons[\alpha]{\gamma} \langle A; \leq \rangle$, $T, B : C \rightarrow C$ are monotone functions satisfying (5) and (6), $T^\#, B^\# : A \rightarrow A$ are monotone functions, such that $\alpha \circ T \circ \gamma \leq T^\#$ and $\alpha \circ B \circ \gamma \leq B^\#$, then the sequence

- $\dot{X}^0 = \text{lfp } T^\#$ (or $\text{lfp } B^\#$)
- $\dot{X}^{2n+1} = \text{lfp}(\lambda X. \dot{X}^{2n} \wedge B^\#(X))$
- $\dot{X}^{2n+2} = \text{lfp}(\lambda X. \dot{X}^{2n+1} \wedge T^\#(X))$

satisfies for all $k \in \mathbb{N} : \alpha(\text{lfp } F \cap \text{lfp } B) \leq \dot{X}^{k+1} \leq \dot{X}^k$

Hence, we have an ascending sequence.

Forwards/backwards analysis over infinite domains

We may also need to *narrow* in order to ensure termination of the downward iteration (if descending chains can be infinite):

$$\dot{X}^0 > \dot{X}^1 > \dot{X}^2 > \dots$$

Similarly, we may need to *widen* (and *narrow*) to ensure termination of the fixed point computation in each iterate.

- $\dot{X}^0 = \text{lfp} \dots$
- $\dot{X}^{2n+1} = \text{lfp}(\dots)$
- $\dot{X}^{2n+2} = \text{lfp}(\dots)$

More fun with the three counter machine

Previously: analysing the 3 counter machine

```
Var ::= x | y | z
Inst ::= inc var | dec var | zero var m else n | stop
States = PC x \N_0 x \N_0 x \N_0
```

Transition relation:

```
<pc, xv, yv, zv> --> <pc+1, xv+1, yv, zv>          if P_pc = inc x
-                   --> <pc+1, xv, yv+1, zv>      if P_pc = inc y
-                   --> <pc+1, xv, yv, zv+1>      if P_pc = inc z

<pc, xv, yv, zv> --> <pc+1, xv-1, yv, zv>          if P_pc = dec x /\ xv>0
-                   --> <pc+1, xv, yv-1, zv>      if P_pc = dec y /\ yv>0
-                   --> <pc+1, xv, yv, zv-1>      if P_pc = dec z /\ zv>0

<pc, xv, yv, zv> --> <pc', xv, yv, zv>             if P_pc = zero x pc' else pc''
-                   --> <pc'', xv, yv, zv>        /\ xv=0
-                   --> <pc'', xv, yv, zv>        if P_pc = zero x pc' else pc''
-                   --> <pc'', xv, yv, zv>        /\ xv<>0

<pc, xv, yv, zv> --> <pc', xv, yv, zv>             if P_pc = zero y pc' else pc''
-                   --> <pc'', xv, yv, zv>        /\ yv=0
-                   --> <pc'', xv, yv, zv>        if P_pc = zero y pc' else pc''
-                   --> <pc'', xv, yv, zv>        /\ yv<>0

<pc, xv, yv, zv> --> <pc', xv, yv, zv>             if P_pc = zero z pc' else pc''
-                   --> <pc'', xv, yv, zv>        /\ zv=0
-                   --> <pc'', xv, yv, zv>        if P_pc = zero z pc' else pc''
-                   --> <pc'', xv, yv, zv>        /\ zv<>0
```

We left off here:

$T\#(S\#) = \emptyset. [1 \rightarrow \{ \langle i, 0, 0 \rangle \mid i \text{ in } N_0 \}]$

U.

U. $\emptyset. [pc+1 \rightarrow \{ \langle xv+1, yv, zv \rangle \}]$
{ $\langle xv, yv, zv \rangle$ } C S#(pc)
P_pc = inc x (...and for y and z)

U.

P_pc = dec x
xv>0 (...and for y and z)

U.

U. $\emptyset. [pc' \rightarrow \{ \langle xv, yv, zv \rangle \}]$
{ $\langle xv, yv, zv \rangle$ } C S#(pc)
P_pc = zero x pc' else pc''
xv=0 (...and for y and z)

U.

U. $\emptyset. [pc'' \rightarrow \{ \langle xv, yv, zv \rangle \}]$
{ $\langle xv, yv, zv \rangle$ } C S#(pc)
P_pc = zero x pc' else pc''
xv<>0 (...and for y and z)

Call-by-need Galois connections :-) (1/3)

Abstracting a set valued function:

Given a Galois connection between complete lattices, we can lift it pointwise to function spaces (also complete lattices):

$$\frac{\langle \wp(C); \sqsubseteq \rangle \begin{array}{c} \xleftarrow{\gamma} \\ \xrightarrow{\alpha} \end{array} \langle A; \sqsubseteq \rangle}{\langle D \rightarrow \wp(C); \dot{\sqsubseteq} \rangle \begin{array}{c} \xleftarrow{\dot{\gamma}} \\ \xrightarrow{\dot{\alpha}} \end{array} \langle D \rightarrow A; \dot{\sqsubseteq} \rangle}$$

where

$$\begin{aligned} \dot{\alpha}(F) &= \lambda d. \alpha(F(d)) \\ \dot{\gamma}(F^\#) &= \lambda d. \gamma(F^\#(d)) \end{aligned}$$

Call-by-need Galois connections :-) (2/3)

Abstracting a set of triples by a triple of sets:

$$\langle \wp(A \times B \times C); \subseteq \rangle \underset{\alpha}{\overset{\gamma}{\rightleftarrows}} \langle \wp(A) \times \wp(B) \times \wp(C); \subseteq_{\times} \rangle$$

between complete lattices (the latter being reduced)
where

$$\begin{aligned}\subseteq_{\times} &= \subseteq \times \subseteq \times \subseteq \\ \alpha(T) &= \langle \pi_1(T), \pi_2(T), \pi_3(T) \rangle \\ \gamma(\langle X, Y, Z \rangle) &= X \times Y \times Z\end{aligned}$$

Call-by-need Galois connections :-) (3/3)

Abstracting a triple of sets by an abstract triple:

Given three Galois connections between complete lattices, we can form a new Galois connection (also over complete lattices):

$$\frac{\begin{array}{ccc} \langle \wp(A); \sqsubseteq \rangle & \begin{array}{c} \xleftarrow{\gamma_A} \\ \xrightarrow{\alpha_A} \end{array} & \langle A'; \sqsubseteq_a \rangle \\ \langle \wp(B); \sqsubseteq \rangle & \begin{array}{c} \xleftarrow{\gamma_B} \\ \xrightarrow{\alpha_B} \end{array} & \langle B'; \sqsubseteq_b \rangle \\ \langle \wp(C); \sqsubseteq \rangle & \begin{array}{c} \xleftarrow{\gamma_C} \\ \xrightarrow{\alpha_C} \end{array} & \langle C'; \sqsubseteq_c \rangle \end{array}}{\langle \wp(A) \times \wp(B) \times \wp(C); \sqsubseteq_{\times} \rangle \begin{array}{c} \xleftarrow{\gamma} \\ \xrightarrow{\alpha} \end{array} \langle A' \times B' \times C'; \sqsubseteq_{\times} \rangle}$$

where

$$\sqsubseteq_{\times} = \sqsubseteq \times \sqsubseteq \times \sqsubseteq$$

$$\sqsubseteq_{\times} = \sqsubseteq_a \times \sqsubseteq_b \times \sqsubseteq_c$$

$$\alpha(\langle X, Y, Z \rangle) = \langle \alpha_A(X), \alpha_B(Y), \alpha_C(Z) \rangle$$

$$\gamma(\langle X', Y', Z' \rangle) = \langle \gamma_A(X'), \gamma_B(Y'), \gamma_C(Z') \rangle$$

Three counter analysis from 10000 feet¹

The Parity analysis is composed in two.

Last week:

$$\overline{\wp(PC \times \mathbb{N}_0 \times \mathbb{N}_0 \times \mathbb{N}_0) \iff PC \rightarrow \wp(\mathbb{N}_0 \times \mathbb{N}_0 \times \mathbb{N}_0)}$$

This week:

$$\frac{\overline{\wp(\mathbb{N}_0 \times \mathbb{N}_0 \times \mathbb{N}_0) \iff \wp(\mathbb{N}_0) \times \wp(\mathbb{N}_0) \times \wp(\mathbb{N}_0)} \quad \frac{\overline{\wp(\mathbb{N}_0) \iff Par} \quad \overline{\wp(\mathbb{N}_0) \iff Par} \quad \overline{\wp(\mathbb{N}_0) \iff Par}}{\wp(\mathbb{N}_0) \times \wp(\mathbb{N}_0) \times \wp(\mathbb{N}_0) \iff Par \times Par \times Par}}{\wp(\mathbb{N}_0 \times \mathbb{N}_0 \times \mathbb{N}_0) \iff Par \times Par \times Par} \quad \overline{PC \rightarrow \wp(\mathbb{N}_0 \times \mathbb{N}_0 \times \mathbb{N}_0) \iff PC \rightarrow Par \times Par \times Par}$$

Hence by transitivity:

$$\overline{\wp(PC \times \mathbb{N}_0 \times \mathbb{N}_0 \times \mathbb{N}_0) \iff PC \rightarrow Par \times Par \times Par}$$

1. and therefore in a very small font

At home: operators/property transformers

At home you calculated abstract operators:

```
=0 : Parity -> Parity
<>0 : Parity -> Parity
+1 : Parity -> Parity
-1 : Parity -> Parity
```

from concrete ones over \mathbb{N}_0 :

```
=0 : \N_0 -> \N_0
    = \S. {s | s in S /\ s=0 }
<>0 : \N_0 -> \N_0
    = \S. {s | s in S /\ s<>0 }
+1 : \N_0 -> \N_0
    = \S. {s+1 | s in S}
-1 : \N_0 -> \N_0
    = \S. {s-1 | s in S /\ s>0 }
```

Result

$T(S\#) = (\langle \text{bot}, \text{bot}, \text{bot} \rangle. [1 \rightarrow \langle \text{top}, \text{even}, \text{even} \rangle])$

U.
